Conclusion

» Context

Sources of faults in a system:

- * Harsh environment
- * Adversary

Risks?

- $\ast~$ Undesired change in a program control flow
- * System crash

Solution?

- 1. Implement countermeasures
- 2. Test them in practice (expertise is required)
- 3. Identify new vulnerabilities
- 4. Repeat

Conclusion

» Fault Injection Simulation

Why would hardware simulation be useful?

- * Does not require expensive equipment
- * No risk to damage important components
- * Allows precise actions on instructions and registers
- * Environment is easy to setup
- * Simulations are fast to perform and reproducible

Ideal to test countermeasures against fault injections.

» Project Description

Objectives:

- * set up simulation environment
- * perform firmware vulnerability analysis
 - $ightarrow\,$ automatic fault injection simulation
 - $ightarrow\,$ SCA feature: cycle count annotation

Setup:

- $\ast\,$ ARM GNU Toolchain: C code compilation
- * Unicorn: CPU emulation
- * Python: simulation tool implementation

 $\ \ \text{Methods}$

Several methods exist to inject faults in a system:

- * Clock fault injection
- * Voltage fault injection
- * Electromagnetic fault injection
- * Optical fault injection

* ...

Unicorn Engine

Conclusion

» Fault Model Characteristics

Two main categories of fault injections:

- * Global: affects global parameters (voltage, clock)
- * Local: precise fault location (expensive equipment)

Fault models are essentially characterized by:

- * Location
 - $\rightarrow~$ Spatial: point or area in the system
 - $\rightarrow~$ Temporal: instant during the execution
 - $\rightarrow~$ Precision level: bit, byte, variable, ...
- * Impact: skip, stuck-at, bit-flip, random byte, ...

- » Countermeasures: Examples
 - * Double check important functions execution
 - * Double check branching conditions
 - * Verify that loops have not been aborted
 - * Avoid boolean values to access critical functions

Overview

- * QEMU-based open-source project
- * CPU emulator

» Unicorn Engine

- * Multiple target architectures (ARM, ARM64, MIPS, RISC-V, ...)
- * Implemented in C, and many bindings exist
- * No requirement regarding emulation context
- * Easy to instrument (hooks on specific events)

Emulation

- » Unicorn Engine
 - 1. Create Unicorn instance
 - 2. Read binary
 - 3. Map program segments into instance memory
 - 4. Prepare initial state/context (optional)
 - 5. Define start and end addresses
 - 6. Add hooks (syscalls, tracing)
 - 7. Run the simulation

Fault Injection

Inject fault using method (1) or (2):

- $1. \rightarrow 6. \ \mbox{Prepare Unicorn instance}$ (see previous slide)
 - 7. Add fault injection hooks (1)
 - 8. Start the simulation
 - 9. Perform fault injection (2):
 - halt simulation
 - * inject fault
 - * resume

Unicorn Engine

- » Description
 - * Based on Unicorn and dedicated to 32-bit ARM architectures
 - * Using Python binding: easy to adapt to your needs
 - * Two command line scripts:
 - $ightarrow\,$ one to explore possible fault attacks
 - $\rightarrow~$ one to perform/reproduce a specific fault attack
 - * User may define external functions:
 - $\rightarrow~$ to set emulation context
 - $ightarrow\,$ to perform fault injection
 - $ightarrow\,$ to extract fault detection flags

Simulation Environment

Conclusion

- » Fault Models
 - * Skip instruction fault model
 - * Register-based fault models:
 - ightarrow "on instruction" fault (transient)
 - $ightarrow\,$ stuck-at fault (permanent)
 - $ightarrow \,$ bit flip fault (transient)
 - * Memory-based fault models:
 - ightarrow "on write access" fault (permanent)
 - ightarrow "on read access" fault (transient)

Fault models are implemented using method (1), i.e. hooks.

» Simulated Execution States

State Set of values extracted from registers and memory regions at a given point of the emulation

Initial state State before the emulation has been started

Final state State after the emulation has been completed

Reference state Final state of a "sane" emulation

» Status of Fault Attacks

- * If fault detection flags are extracted through external functions:
 - $\rightarrow~$ fault is ignored if detection flag was raised,
 - $\rightarrow~$ otherwise, fault injection may be logged.

- * Logging of fault injections works as follows:
 - $\rightarrow~$ fault injection is logged if a delta appears between the final state and the reference state,
 - $\rightarrow~$ otherwise, fault injection is ignored.

Conclusion

- » Exploration of Fault Attacks Space
 - 1. Select desired fault models
 - 2. Try to perform a fault injection attack:
 - $\rightarrow~$ for each fault model,
 - $ightarrow\,$ for each instruction,
 - $ightarrow \,$ depending on written/read registers (if register-based),
 - $\rightarrow~$ for each value of the fault model parameters.
 - 3. Identify the status of the fault attack
 - 4. Log it if necessary

Note: limited set of values for each parameter of the different fault models

- » Conclusion
 - * Allows to inject faults in program running on specific architectures
 - * Should be useful to check if countermeasures work as expected
 - * Should allow to detect unknown vulnerabilities
 - * Does not allow to test all specific countermeasures (e.g. delay-based)
 - * Emulation of peripherals on a high level should be possible
